

Random recipes seemed like a good idea for inspiration, and this was pretty easy to implement given that the API call was very similar. There was only a small change in how ingredients were parsed.

Error checking and alerts were added for searches (no results returned) as well as API errors to alert the user and explain that there has been some kind of error.

Pricing and nutrition information were a bit trickier to add, but I think still add value to the user in deciding which recipes they might want to try. There is a concern regarding the API key in the image paths, which I'm not sure how to resolve easily, even after external research. And the API image returned for the pricing is not exactly as expected based on what was shown on the API docs; tried to make up for this with a last ditch API call to get numerical pricing information to supplement the bare pie chart provided.

There is some room for improvement in this area, but I think this project is at the level I'd feel comfortable submitting it at; I think it demonstrates my ability to apply the knowledge shared in the course so far, and a bit beyond. I would absolutely ensure that the shortcomings outlined above would definitely be remedied before this were to go into a production environment.
